

Unit 3 Assessment

Task 1

Sequence diagram for

“As a local vendor,
I want a dashboard where I can track my inventory levels,
So that I can keep my products in stock without having to contact the platform owner.”

Activity diagram for

“As a customer,
I want a search tool that accounts for location,
So that I can find goods that were sourced near me.”

Class diagram for

“As a data entry technician,
I want a simple form in the site admin portal,
So that it’s easy to publish new listings and describe their contributions to
community and environmental stewardship.”

Task 2

Task 3

The recommendation I would adopt for Northern Green:

“(06) Limit computational accuracy of the application to the desired level which commensurate with the operational needs. For example, you do not need very high resolution geolocation data of your user, if you are just looking for friends nearby.”

I would use this advice for the idea in the activity diagram from task 1. Matching customers with local vendors will be accurate enough, but some accuracy is compromised to ensure low computational cost. Instead of calculating exact distance or travel time for every vendor, the approach simply queries the database for vendors within a coordinate range.
